

A Two-Phase Dynamic Programming Algorithm Tool for DNA Sequences

Oyelade Jelili & Fatumo Segun

Abstract:

Sequence alignment has to do with the arrangement of DNA, RNA, and protein sequences to identify areas of similarity. Technically, it involves the arrangement of the primary sequences of DNA, RNA, or protein to identify regions of similarity that may be a consequence of functional, structural, or evolutionary relationships between the sequences. Similarity may be a consequence of functional, structural, or evolutionary relationships between the sequences in an alignment share a common ancestor, mismatches can be interpreted as mutations, and gaps as insertions. Such information becomes of great use in vital areas such as the study of diseases, genomics and generally in the biological sciences. Thus, sequence alignment presents not just an exciting field of study, but a field of great importance to mankind. In this light, we extensively studied about seventy (70) existing sequence alignment tools available to us. Most of these tools are not user friendly and cannot be used by biologists. The few tools that attempted both Local and Global algorithms are not ready available freely. We therefore implemented a sequence alignment tool (CU-Aligner) in an understandable, user-friendly and portable way, with click-of-a-button simplicity. This is done utilizing the Needleman-Wunsh and Smith-Waterman algorithms for global and local alignments, respectively which focuses primarily on DNA sequences. Our aligner is implemented in the Java language in both application and applet mode and has been efficient on all windows operating systems.

Keywords — sequence, global alignment, local alignment, dynamic programming and java applet.

1. INTRODUCTION

DNA sequencing is a process of determining the exact order of over 3 billion chemical building blocks i.e. the A, C, T, and G bases that make up the DNA. This process was an important scientific discovery, as before sequencing was actually done, it was assumed that DNA consisted hundreds of thousands of genes. Upon performing sequencing, though, it was realized that there are approximately 20000-25000 genes in the human DNA. It is with the foundation of sequencing that sequence alignment has relevance.

According to Batzoglou [1], sequence alignment is the analysis of the sequence of the elements of genes or proteins. It involves the arrangement of DNA, RNA, or protein sequences to identify regions of similarity between them. Such similarity may be a consequence of functional, structural, or evolutionary relationships between the sequences. If two sequences in an alignment share a common ancestor, mismatches can be interpreted as mutations. Aligned sequences of nucleotide or amino acid residues are represented as rows within a matrix. Gaps are introduced between the residues so residues with identical or similar characters are aligned in the successive columns.

In situations where two sequences in an alignment share a common ancestor, mismatches can be interpreted as point mutations and gaps as indels (that is, insertion or deletion mutations) introduced in either or both of the mutations in the period within which they diverged from one another. In protein sequence alignment, the degree of similarity between amino acids occupying a particular position in the sequence can be interpreted as a rough measure of how conserved a particular region or sequence motif is among lineages. The absence of substitutions, or the presence of only very conservative substitutions (that is, the substitution of amino acids whose side chains have similar biochemical properties), in a particular region of the sequence, suggests that such a region has structural or functional importance. Though DNA and RNA nucleotide are more similar to each other than to amino acids, the conservation of base pairing still can indicate a similar functional or structural role. It is of course of some importance to note that sequence alignment can be used for non-biological sequences, such as those present in financial data or in natural language [9]. In the light of this, we observe that sequence alignment can be used to identify similarities in a series of letters and words present in human language.

2. PROBLEM STATEMENT

Very short and similar sequences can adequately be aligned by hand, but most interesting problems require lengthy, highly variable or extremely numerous sequences which cannot be aligned solely by human effort. We can see, for example that two 12 residue sequences, would require considering approximately one million alignments, and two 150 residue sequences would require considering approximately 10 88 alignments (interesting considering that 10⁷⁸ is the estimated number of atoms in the universe). Hence, human effort is thus applied in formulating algorithms to simplify and reduce such a lengthy process, and also occasionally in adjusting results to reflect patterns difficult to express algorithmically. Computational approaches to sequence alignment generally fall into two categories, these being Global and Local Sequence Alignment [2].

2.1 Pair wise Alignment

Pair wise sequence alignment methods, are used to find the best matching local or global alignments of two query sequences. It can only be utilized when considering two sequences at a time, and are often used for methods that do not require extreme precision. The three primary techniques for pair wise alignment are Dot-Matrix methods, Dynamic Programming, and Word Methods, though multiple sequence alignment techniques can be used to solve pair wise alignment cases. All three methods have their strong and weak points, but all have difficulty with highly repetitive sequences of low information content, especially where the number of repetitions differs in the two sequences to be aligned.

2.2 Smith-Waterman algorithm

The Smith-Waterman algorithm was first proposed by Temple Smith and Michael Waterman in 1981. It is a well-known algorithm for performing local sequence alignment [7]; that is, for determining similar regions between two nucleotide or protein sequences. Instead of looking at the total sequence, the Smith-Waterman algorithm compares segments of all possible lengths and optimizes the similarity measure

2.3 Needleman-Wunsch algorithm

The Needleman—Wunsch algorithm performs a global alignment on two sequences. It is commonly used in bioinformatics to align protein or nucleotide sequences [8]. The Needleman—Wunsch algorithm is an example of dynamic programming, and was the first application of dynamic programming to biological sequence comparison.

2.4 Dynamic Programming

Global alignments, which attempt to align every residue in every sequence, are most useful when the sequences in the query set are similar and of roughly equal size. Local alignments are more useful for dissimilar sequences that are suspected to contain regions of similarity or similar sequence motifs within their larger sequence context. Very common and useful alignment techniques for the implementation of global and local sequence alignment are Needleman Wunsch and Smith Waterman algorithms [8]. These techniques are based on the dynamic programming principle.

Dynamic Programming Principle: The technique of dynamic programming is theoretically applicable to any number of sequences; however, because it is computationally expensive in both time and memory, it is rarely used for more than three or four sequences in its most basic form. This method requires constructing the ndimensional equivalent of the sequence matrix formed from two sequences, where n is the number of sequences in the query. Standard dynamic programming is first used on all pairs of query sequences and then the "alignment space" is filled in by considering possible matches or gaps at intermediate positions, eventually constructing an alignment essentially between each two-sequence alignment. Although this technique is computationally expensive, its guarantee of a global optimum solution is useful in cases where only a few sequences need to be aligned accurately.

The dynamic programming principle involves three (3) major steps:

- Initialization: This is the first step in dynamic programming. It involves the creation of a matrix with M+ 1 column and N+ 1 row, where M and N are the sizes of the sequences to be aligned.
- **2.** Matrix fill (scoring): This is where each cell in the created matrix is filled with calculated values.
- Trace back (alignment): The trace back step simply determines the actual alignment that results in a maximum score.

This work, utilizes the Needleman-Wunsch and Smith-Waterman algorithms, which are examples of dynamic programming, to implement the pairwise sequence alignment of DNA sequences. CU-Aligner is a standalone application but can also be deployed over the internet, thus being available to a much wider audience.

In Table 1, we show list of existing sequence alignment tools available with brief description of the feature they offer.

3. BASIC FEATURES OF CU-ALIGNER

Our tool presents the following features together. It makes the work of a biologist easier.

User-Friendly Nature- CU-Aligner presents what could otherwise be a cumbersome task by hand, in a plain and understandable format with click-of-a-button simplicity in carrying out alignments. Also its specialization in focusing on DNA sequences aids its simplicity. This is a solution to situations where multiple functionality of aligners, adversely affect understandability of such programs.

Portability- As this Aligner has been implemented in the Java language it presents the advantage of being able to be

Table 1: List of different sequence alignment tools available and their features

S/N	Name	Description	Sequence Type	Alignment Type	Author	Year

run on all platforms, this being possible as a result of the portable nature of the Java Language.

Understandable Output- CU-Aligner presents the result of an alignment in a manner not requiring special knowledge to understand. It also presents results as soon as they are computed, as opposed to a situation where output is sent to the user at a later time.

Open Source: CU-Aligner is offered free of charge upon request.

Flexibility- CU-Aligner presents a user with the choice of parameters to use in performing an alignment, these being the gap penalty, the match and mismatch scores.

4. MATERIALS AND METHODS

CU-Aligner was implemented in the Java language in both application and applet mode. Deployment on to a web page can be done with simple coding statements once, the web page is built using Macromedia Dreamweaver.

5. DESIGN OF CU-ALIGNER

CU-Aligner is designed based upon the Needleman-Wunsch and Smith-Waterman algorithms (Wunsch and Waterman 1970), for Global and Local alignments, respectively. The aligner program implements each stage of each algorithms implementation: These being, the Initialization, Matrix-Fill and Trace back Stages as depicted in the figure 1, 2 and 3. The flow of the CU-Aligner is given is figure 4.

		G	Α	Α	Т	T	C	Α	G	т	T	Α
	0	0	0	0	0	0	0	0	0	0	0	0
G	0											
G	0					3 -						
Α	0											
т	0					8 1		0 V				
T	0											
G	0							2 -				
Α	0											

Figure 1: Initialization

The first step in the global alignment dynamic programming approach is to create a matrix with M+1 columns and N+1 rows where M and N correspond to the size of the sequences to be aligned.

		G	Α	Α	Т	Т	CA		G	Т	Т	A
	0	0	0	0	0	0	0	0	0	0	0	0
G	0	1	1	1	1	1	1	1	1	1	1	1
G	0	1	1	1	1	1	1	1	2	2	2	2
Α	0	1	2	2	2	2	2	2	2	2	2	3
Т	0	1	2	2	3	3	3	3	3	3	3	3
С	0	1	2	2	3	3	3	4	4	4	4	4
G	0	1	2	2	3	3	3	4	4	5	5	5
Α	0	1	2	3	3	3	3	4	5	5	5	6

Figure 2: Matrix-Fill

This is where each cell in the created matrix is filled with calculated values.

In order to find $M_{i,j}$ for any i,j it is necessary to know the score for the matrix positions to the left, above and diagonal to i, j. In terms of matrix positions, it is necessary to know $M_{i-1,i}$, $M_{i,i-1}$ and $M_{i-1,i-1}$. i.e.

$$G[i, j] = \max \begin{cases} G[i - 1, j - 1] + s(x_i, y_j) \\ G[i - 1, j] + g \\ G[i, j - 1] + g \end{cases}$$

$$G[0, j] = j \cdot g, \quad j \in [0, \dots, n]$$

$$G[i, 0] = i \cdot g, \quad i \in [0, \dots, m]$$

		G	Α	Α	Т	Т	С	Α	G	Т	Т	Α
	0	0	0	0	0	0	0	0	0	0	0	0
G	0	1	1	1	1	1	1	1	1	1	1	1
G	0	1	1	1	1	1	1	1	2	2	2	2
Α	0	1	1	2	2	2	2	2	2	2	2	3
Т	0	1	2	2	3	3	3	3	3	3	3	3
С	0	1	2	2	3	3	4	4	4	4	4	4
G	0	1	2	2	3	3	4	4	5	5	5	5
Α	0	1	2	3	3	3	4	5	5	5	5	- 6

Figure 3: Traceback

The traceback step determines the actual alignment(s) that result in the maximum score. Note that with a simple scoring algorithm such as one that is used here, there are likely to be multiple maximal alignments. The traceback step begins in the M,J position in the matrix, i.e. the position that leads to the maximal score. In this case, there is a 6 in that location.

Traceback takes the current cell and looks to the neighbor cells that could be direct predecessors. This means it looks to the neighbor to the left (gap in sequence #2), the diagonal neighbor (match/mismatch), and the neighbor above it (gap in sequence #1). The algorithm for traceback chooses as the next cell in the sequence one of the possible predecessors. They are all also equal to 5.

Since the current cell has a value of 6 and the scores are 1 for a match and 0 for anything else, the only possible predecessor is the diagonal match/mismatch neighbor.

If more than one possible predecessor exists, any can be chosen. This gives us a current alignment of :

Continuing on with the traceback step, we eventually get to a position in column 0 row 0 which tells us that traceback is completed. One possible maximum alignment is:

And an alternate derived from the same procedure:

There are more alternative solutions each resulting in a maximal global alignment score of 6. Since this is an

exponential problem, most dynamic programming algorithms will only print out a single solution

The same principle is followed in the implementation of the Smith-Waterman algorithm, except that the matrix is filled on the following basis:

$$L[i,j] = \max \begin{cases} L[i-1,j-1] + s(x_i,y_j) \\ L[i-1,j] + g \\ L[i,j-1] + g \\ 0 \\ L[0,j] = 0, \quad j \in [0,\dots,n] \\ L[i,0] = 0, \quad i \in [0,\dots,m] \end{cases}$$

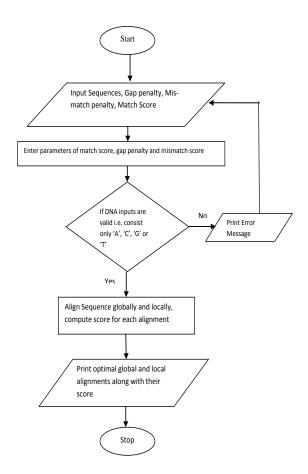

Figure 4: Flowchart of Pairwise Aligner

6. RESULTS

The pairwise aligner accepts two DNA sequences (see figure 5) and produces their global and local alignments, as well as their scoring matrix (see figure 6 and 7 respectively). A deployable version if CU-Aligner on the internet is shown in figure 8.

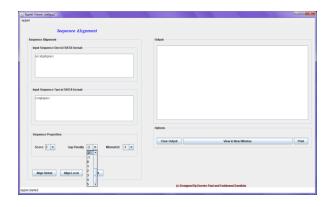

Figure 5: Pairwise Aligner Interface

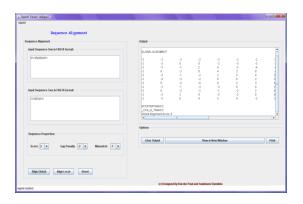

Figure 6: Local Alignment

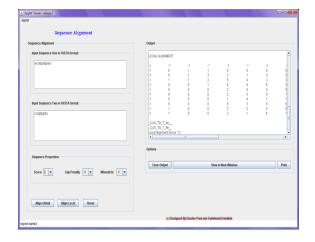

Figure 7: Local Alignment

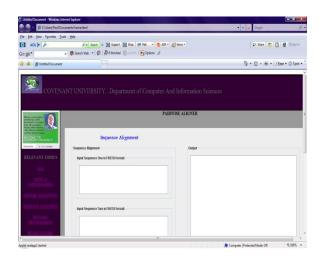

Figure 8: Applet Deployed On Web Page

A user, on accessing the pairwise aligner, enters in both sequences in the appropriate fields. Parameters are then selected so as to carry out the alignment as the user desires in terms of the match score, gap penalty and mismatch score.

On clicking the global alignment button, a check on inputted sequences is made to ensure compliance of the inputted sequences to DNA sequence structure (i.e. consisting alphabets A, C, G, and T). Once this check is cleared the two sequences are globally aligned.

In the case of local alignment, the same process takes place, except that the output is the local alignment of the two sequences.

7. CONCLUSION

Sequence alignment can be a useful technique for studying molecular evolution and analyzing sequence-structure relationships. We present a sequence alignment tool in an understandable, user-friendly and portable way, with click-of-a-button simplicity. This is done utilizing the Needleman-Wunsh and Smith-Waterman algorithms for global and local alignments, respectively which focuses primarily on DNA sequences. Our aligner is implemented in the Java language in both application and applet mode and has been tested working efficiently on all windows operating systems.
